Executive Summary

This report investigates the analysis of ESG, governance, and financial performance in nine Asia-Pacific countries, including Australia, Bangladesh, China, India, Indonesia, the Republic

of Korea, Malaysia, New Zealand and Singapore, from 2010 to 2024 by using Tableau tools to make a story that provides three dashboards. Therefore, the analysis will explore the regional by ESG trend, governance drivers, and the relationship between ESG and financial performance outcomes. There are 3 dashboards that show the analysis and relationship. Dashboard 1 presents the market value and ESG performance, both of which are affected by country and industry composition. This means ESG might not rely on a single country. Dashboard 2 highlights governance factors, including female board representation, CEO duality, and ESG controversies. It can encourage the explanation of differences in ESG performance. Dashboard 3 shows that ESG might rely on profitability outcomes, including ROA, Tobin's Q, and MTB, and also forecasts the trend through 2028. However, the dataset has some limitations. For example, the ESG of Bangladesh and New Zealand are smaller markets, leading to missing data in the time series. Also, providing recommendations to firms, stakeholders, and policymakers to improve the dataset and assess the future value of the economy.

1. Introduction

The purpose of this report is to analyse ESG, governance, and financial performance across nine Asia-Pacific markets from 2010 to 2024 using a Tableau Story. This can identify ESG performance associated with governance, financial, and country-firm value, such as ROA, Tobin's Q, and MTB. According to Li et al. (2026), ESG is a sustainability topic that is crucial globally because it may support investors to access company sustainability, which can reduce climate change issues in the long term and also reduce risk and regulatory pressure; however, it can offer opportunities in the long-term value and create market value in Asia-Pacific to stakeholders to make decisions to invest easily. Therefore, this report uses a dataset which are implemented in Australia (AASB S1/S2 from January 2025), New Zealand (NZ CS standards under XRB), Singapore (SGX climate rules), Hong Kong and mainland China (HKEX/CSRC guidelines), Korea (KSSB) and India (SEBI BRSR Core), broadly converging with the IFRS Foundation's ISSB standards. Additionally, the analysis examines ESG performance and how governance factors drive measurable financial outcomes.

2. Findings and Critical Analysis

The section will explore and examine the analysis results from three dashboards, which will show the Asia-Pacific Market Landscape, Governance Drivers, and ESG and financial Performance in section 2.1, 2.2, and 2.3

2.1 Dashboard 1: Asia Pacific Market Landscape

This dashboard examines ESG, financial performance, and industry across nine Asia Pacific markets, using regional baselines. The dashboard presents a KPI table summarising average ESG Pillar scores, market capitalisation, total MCAP in USD billion, ROA, and Tobin's Q across ESG coverage. The ESG results show that ESG's ability is generally unstable across markets in 9 Asia-Pacific countries, especially in developed countries such as Australia, New Zealand, Singapore, and South Korea. As a result, the mean average of these countries is higher than that of other countries, such as Bangladesh, China, India, Indonesia, and Malaysia)

because these countries are stronger and improve faster, which is shown in the line chart. Moreover, the choropleth map illustrates market value, with a focus on larger markets such as China and India. In contrast, the smaller markets are New Zealand and Bangladesh, which have a low regional MCAP. The top 10 industries chart, such as materials, Bank, and the IT industry, shows the largest MCAP values, which are not associated with ESG value. This is a financial scale, and ESG performance needs to be interpreted separately. Thus, the difference between ESG and governance may influence other economic values (Chau et al. 2025).

2.2 Dashboard 2: Governance Drivers

In this dashboard, explore the ESG pillar from government and industry perspectives. This study will analyse the ESG pillars, where Governance (G) shows a strong pillar across industry groups, and Environmental (E) is variable, especially in the Materials and Energy industries due to high carbon emissions. This means industry value also affects and drives ESG value. Furthermore, the scatter plot shows a positive relationship between ESG score and female on Board (FOB). According to Chebbi et al. (2024) this, board composition can influence corporate objectives. Although the CEO duality might affect the leadership structure, it does not affect the governance factor in ESG results. Another map is a heat map showing countries by year from 2010 to 2024. The ESG score differences are presented, with Korea, India, Indonesia, and Singapore improving over time. Although China has a low improvement level, it improved in 2024. The controversy chart also presents the controversy risk across different industries, measured by median. The measurement of controversy results is LSEG, which is inverse: a controversy score of 100 means no controversy, and a lower score indicates a higher risk. This result shows that the debate over ESG can affect investor decisions and business value.

2.3 Dashboard 3: ESG and Financial Performance

This dashboard shows the ESG score for financial metrics such as ROA, Tobin's Q, and MTB. The scatter plot shows a slightly positive trend between ESG scores and ROA, suggesting that higher ESG scores may be associated with higher profitability. Also, it provides a filter ROA range of -1 to +1 to reduce extreme outliers that can affect interpretability. Moreover, ESG and Tobin's Q are forecast to trend in 2028 based on the average ESG score. The result explains that the trend will increase gradually to 2028, while Tobin's Q remains stable. On the other hand, the prediction is 95%, with uncertainty shown. Furthermore, ESG high threshold parameters indicate that results are high or low, so the default threshold is 70, meaning ESG values greater than 70 are classified as High ESG. For instance, if the ESG score is 72, it will be high when the threshold is 70; however, if it ranges from 75, it will be low ESG. Therefore, ESG financials may not affect the Asia Pacific market, as a high ESG score can lead to higher ROA and Tobin's Q. Threshold analysis can encourage businesses to examine how ESG changes affect classification, sample size, and average financial performance, especially in small markets.

3. Critical reflection

There are several limitations in this study, as indicated by the dashboard results. Firstly, the dataset is not fully analysed because the ESG dataset is global, filtered to years 2010 to 2024, and contains only non-null values. In the instruction material, the ESG score data are 17,368

firm-year observations from a 237,506 firm-year dataset. However, we filter by 2010-2024, which shows 16,752, so there is a small problem with this. The dataset shows only 8 countries. Bangladesh has disappeared because it is a small market and has fewer ESG observations, which means the result should be interpreted because ESG coverage is focused on large firms. As a result, it can lead to missing values, which might be misinterpreted. Another limitation is that financial ratios, such as ROA, may be influenced by outliers due to the filter method. Finally, the limitation is the threshold that shows High and Low ESG. This means the result might not be stable, as the thresholds range from 50 to 80. Thus, a small market might have a high threshold value.

4. Recommendations

Firms: ESG can enhance governance quality, such as business strategy, by providing dashboards that highlight industry controversy (Marfu et al. 2025). It can help reduce risk and strengthen ESG management, thereby benefiting stakeholders in their decision-making, because Dashboard 2 indicates that governance and controversy risk help to explain variation in ESG scores. Also, aligning sustainability can help firms improve the quality of reporting aligned with the ISSB.

Investors: Improving decision-making for stakeholders should use the ESG score because it can provide different value than ROA, Tobin's Q, and MTB, which rely on industry, country, and year. Moreover, stakeholders should be concerned about differences in ESG scores because thresholds vary across markets (Tabur and Bildik 2025).

Regulators: It should improve and compare ESG scores aligned with the ISSB frameworks, including ASIC/AASB, NZ FMA/XRB, MAS, SEBI, CSRC/HKEX, and KSSB. This can help stakeholders make decisions more easily and reduce long-term risk.

5. Conclusions

To sum up, this study presents an analysis of the Asia-Pacific market in 9 countries from 2010 to 2024 using a Tableau story. It demonstrates ESG Scores, which align with governance, industry, and financial outcomes. As a result, the high value of ESG can drive profitability and market valuation. However, some results may be limited by datasets from Bangladesh and New Zealand, which have low ESG scores. Also, forecasting the average ESG score and Tobin's Q to 2028. This analysis may lead to a strong business strategy, better stakeholder decisions, and stronger regulations in the long term.
